

CODENATION (MANIT)

1)

The screenshot shows a web browser window with the URL <https://www.interviewbit.com/test/b3fca240c7/?signature=BAhpA1EwEg%...>. The page is titled "Good arrays" and is part of a test for "Trilogy Innovations" on "17th July 2022". The test timer shows "01 Hr : 53 min : 56 sec" and the progress is "0 / 4 Attempted".

Good arrays

You have an array of N integers. You need to make this array good. An array $A_1, A_2, A_3 \dots A_N$ considered to be good if $A_1 > A_N$. In order to make it good you can swap any two numbers in the array. Also you can perform this operation any number of times on any adjacent pairs of integers in the array A . Find the number of ways in which you can make this array good.

NOTE - Two ways are considered same if resulting array after making all the swaps have same A_1 and A_N .

Input

First argument of input contains an array of size N denoting $A_1, A_2, A_3 \dots A_N$ respectively.
($1 \leq A_i \leq 10^4$)
($1 \leq N \leq 10^5$)

Output

Return an integer which is the number of ways in which you can make given array good.

Examples

Input

1 4 3 2 5

Output

10

Explanation

Testcase 1-

2)

The screenshot shows the InterviewBit website interface. The top navigation bar includes the InterviewBit logo, the date 'Trilogy Innovations 17th July 2022', a timer '01 Hr : 46 min : 22 sec', and a progress indicator '1 / 4 Attempted'. The main content area is titled 'Perfect sets' and contains the following sections:

- Problem Description:** Given an Array A consisting of N balls. All the balls are either "Red" or "Green". You can **pick 4 balls** from the given array(not necessarily consecutive), to form a set. A set of 4 balls is said to be perfect if it contains:
 - Two red followed by two green balls, i.e "RRGG".
 - Two green followed by two red balls, i.e "GGRR".You have to count the number of possible ways of forming a perfect set out of the given balls.
- Problem Constraints:**
 - $1 \leq |A| \leq 10^5$
 - $A_i = 'R'$, if i^{th} ball is "Red".
 - $A_i = 'G'$, if i^{th} ball is "Green".
- Input Format:** The first and only argument is string A , which describes the balls in the array.
- Output Format:** Return an integer denoting the number of possible perfect sets which you can form.
- Example Input:**
 - Input 1:
 $A = "RGRRGR"$
 - Input 2:
 $A = "GRGGRR"$
- Example Output:**
 - Output 1:
0
 - Output 2:
3
- Example Explanation:**
 - Explanation 1:
There is no way possible to form "RRGG" or "GGRR" in the given string.
 - Explanation 2:
There are 3 ways to form "GGRR" by choosing indices as: $\{0,2,4,6\}$, $\{0,3,4,6\}$ and $\{2,3,4,6\}$.

Minimize Marked Fruits

Flag Question

Problem Description

You are a fruit seller, and wants to sell your **A** fruits. Currently, the fruits are arranged in a line with i^{th} fruit to the left of $(i+1)^{\text{th}}$ fruit for, $1 \leq i \leq A-1$. The size of fruits are represented by an array **B** ($B[i]$ representing the size of i^{th} fruit) such that size of each fruit is unique.

To make your fruits smell nice you can put certain essence on some of the fruits. But the essence is quite costly, so you want to minimize its usage such that the following conditions are satisfied:

- You should put essence on atleast 1 (one) fruit.
- If you put essence on i^{th} fruit, then you also have to put essence on each fruit which has a size greater than i^{th} fruit.
- There should exist atleast 1 (one) subarray (contiguous subsegment) of size atleast **C**, such that the number of fruits with essence on it is greater than the number of fruits without essence on it.

Return the smallest number of fruits on which you should put essence such that the above conditions are satisfied.

Problem Constraints

$1 \leq A \leq 10^5$
 $1 \leq B[i] \leq A, (1 \leq i \leq n, B[i] \neq B[j])$
 $1 \leq C \leq A$

Input Format

First argument **A** is the number of fruits.
Second argument **B** is an array representing the size of fruits.
Third argument **C** is the minimum length of subarray according to the condition defined in problem statement.

InterviewBit Trilogy Innovations 17th July 2022 01 Hr : 41 min : 36 sec 1 / 4 Attempted End Test

Output Format

Return a single integer representing the minimum number of fruits on which you will put essence.

Example Input

Input 1:
 $A = 5$
 $B = [2, 3, 5, 1, 4]$
 $C = 3$

Input 2:
 $A = 4$
 $B = [2, 3, 1, 4]$
 $C = 2$

Example Output

Output 1:
2

Output 2:
2

Q 2

Q 3

Q 4

S1

Q 1

Q 2

Q 3

Q 4

Example Explanation

For Input 1:
We can put essence on fruits at index 3 and at index 5 (1-based indexing).
Now, subarray [3, 5] is of size atleast 3, and it has greater number of fruits with essence in comparison to fruits without essence.
We can prove that this is the smallest number of fruits on which we can put essence.

For Input 2:
We can put essence on fruits at index 2 and 4 (1-based indexing).
Now, subarray [2, 4] is of size atleast 2, and it has greater number of fruits with essence in comparison to fruits without essence.
We can prove that this is the smallest number of fruits on which we can put essence.

You only need to implement the given function. Do not read input; instead use the arguments to the function. Do not print the output; instead return values as specified. Still have a question? Check out Sample Codes for more details.

Incorrect Binary Search
 Flag Question

Problem Description

Given pseudocode below to find i from l to r (both inclusive) :

```

while (l < r) {
    int mid = (l + r) / 2;
    if (i < mid)
        r = mid - 1;
    else if (i > mid)
        l = mid + 1;
    else {
        print("Found");
        break;
    }
}
  
```

You have to answer q queries, where in each query, you will be given l and r . Then for each query, answer the following:

What is the probability that the above code will give an incorrect answer (does not print 'Found') while choosing any value i ($l \leq i \leq r$) ? Express the probability as an integer where the fraction is P/Q and $\gcd(P, Q) = 1$. You should compute $P * Q^{-1} \text{ modulo } 10^9+7$, where Q^{-1} denotes the multiplicative inverse of Q modulo 10^9+7 .

Problem Constraints

$1 \leq A[i][0] \leq A[i][1] \leq 10^6$

Input Format

The first argument is a 2D integer array A , denoting the queries l and r in each row

Output Format

Return an integer array denoting the probability in the form $P * Q^{-1} \text{ modulo } 10^9+7$ for each query.

Example Input

Input 1:

```

A = [
    [2, 9]
]
  
```

Input 2:

```

A = [
    [10, 10]
    [10, 12]
]
  
```

Trilogy Innovations 17th July 2022

01 Hr : 41 min : 03 sec

1 / 4 Attempted

End Test

Q 1

Q 2

Q 3

Q 4

Example Output

Output 1:
[500000004]

Output 2:
[1, 666666672]

Example Explanation

Explanation 1:
The numbers 2, 4, 6, 9 will give incorrect answer.
So, the probability is $4 / 8 = 1 / 2$, hence $1 * \text{modInverse}(2) = 500000004$

Explanation 2:
Since, l and r are equal, the loop won't even run once, so the probability is 1.
Only 11 will be found, so the probability is 666666672.
